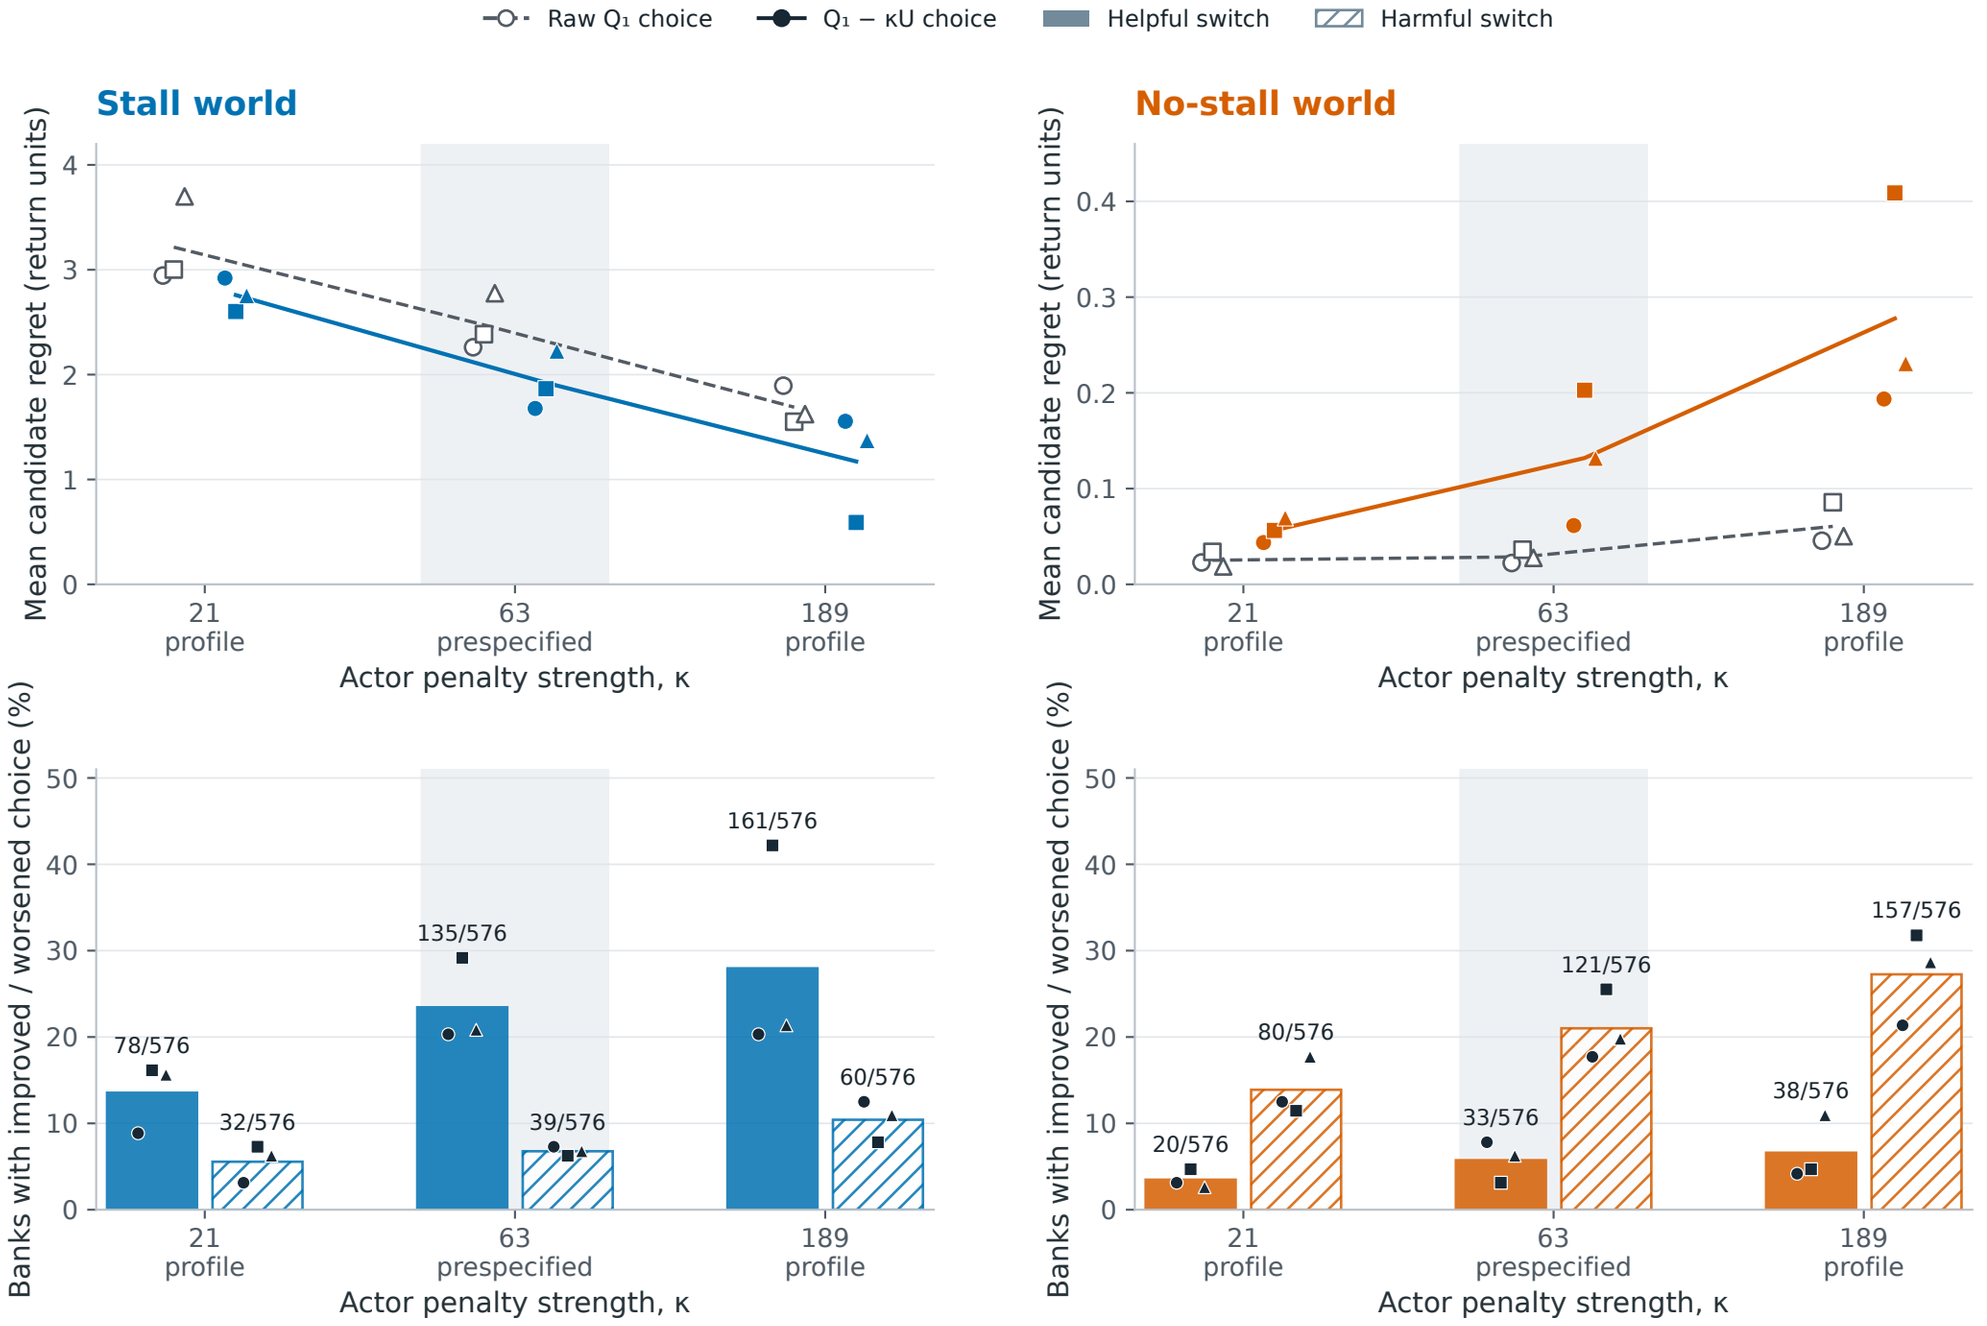
How the penalty changes candidate choices

Retrospective four-candidate banks: logged action plus three withheld a_0 commands; lower regret is better.



192 shared state banks × 3 final policies = 576 evaluations per dose/world, not independent states. Seeds: circle 0, square 1, triangle 2.
Regret uses each policy's own Qπ continuation. This is not deployed actor behavior or proof of the return mechanism. Top-panel scales differ.
