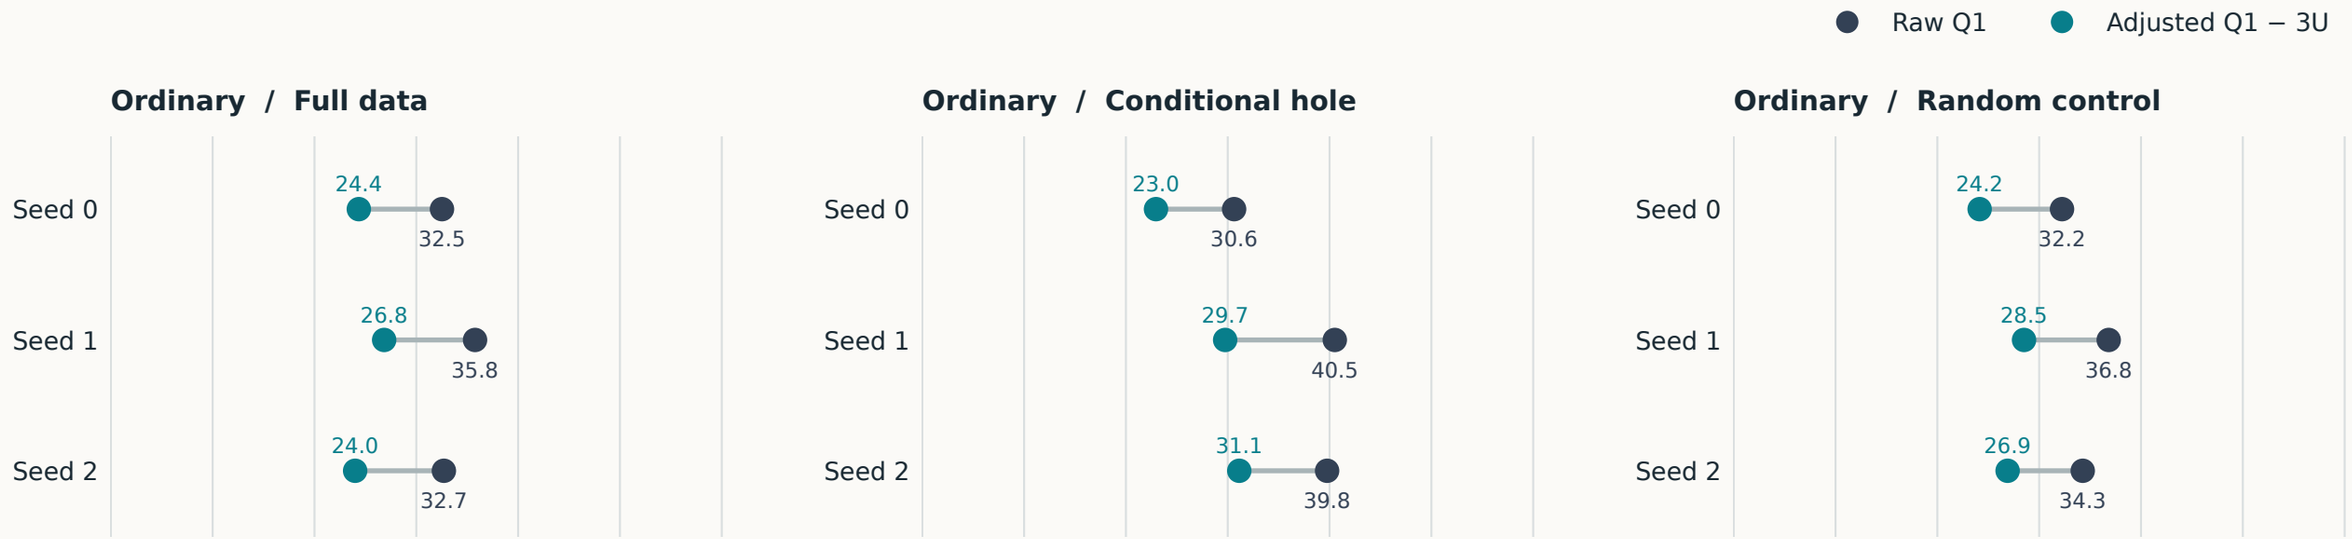
Accuracy on states each policy actually visits

BCA-trained critics, free-policy trajectories | Same visited action and discounted reward suffix in each pair | Final checkpoint



32 episodes per seed and context, sampled at t = 0, 25, 50 and 75 (128 dependent rows). Smaller MAE is better.
These are freely visited actions, not the forced-action anchor bank; the observed removal-mask label does not establish local joint support.
MAE = mean absolute error in discounted-return units; U = BCA uncertainty score. Source: authenticated report 55cae667d369.
