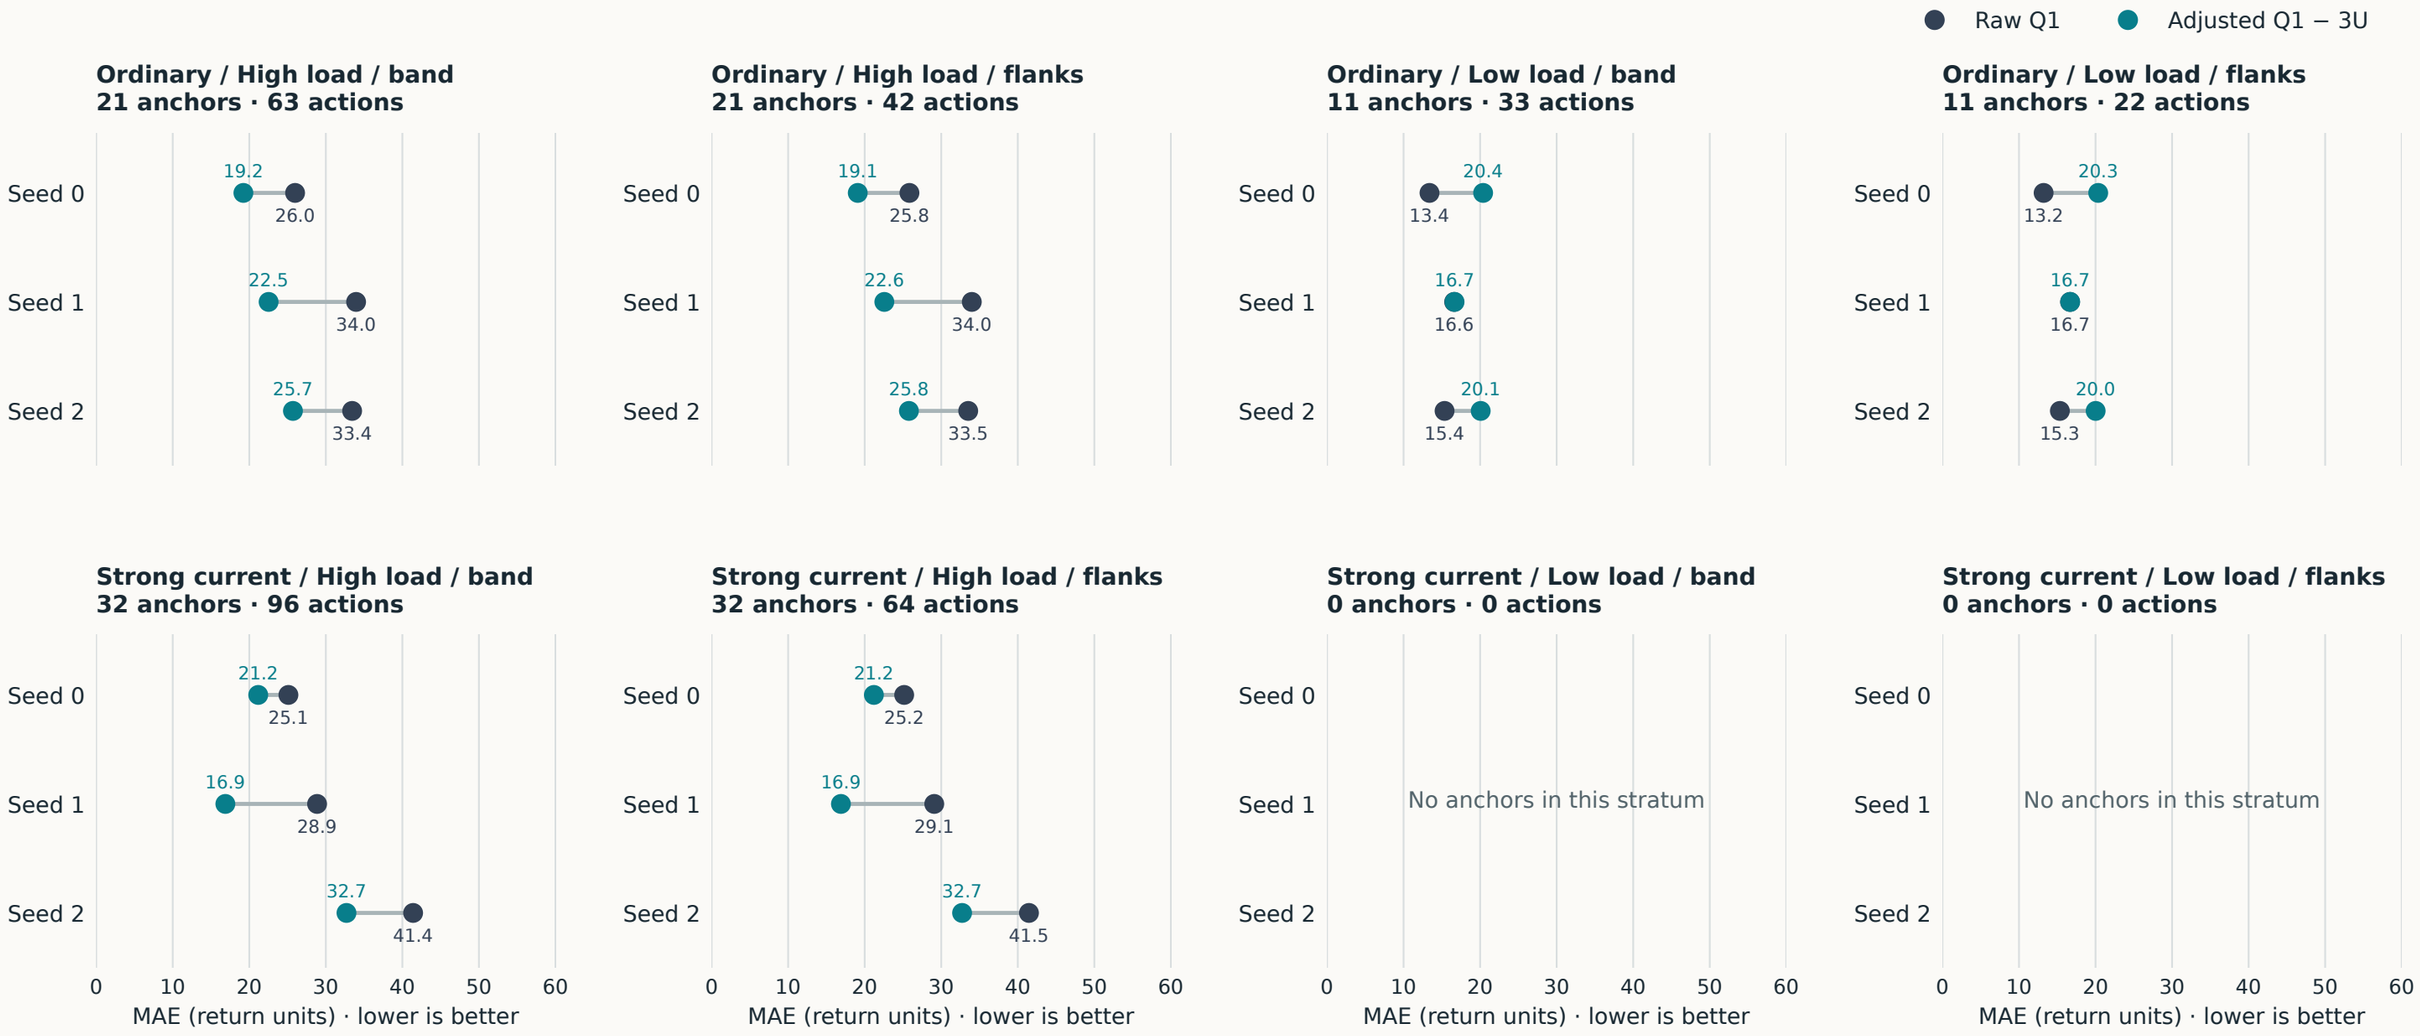
Where does the score adjustment change accuracy?

Conditional-hole BCA critic | Fixed complete actions | Same-critic raw and adjusted MAE, by training seed



Band actions: $a_0 = -0.25, 0, +0.25$. Flanks: $a_0 = -0.5, +0.5$; remaining commands are zero. High/low load also changes the state distribution.
Strong-current anchor bank has no low-load anchors. These action rows share states; no joint support or causal effect of load is established.
